

1. Relative position statements helped to describe where the shapes were from both directions (left/right and up/down). Two circles were described as creating a venn diagram, which helped us visualize where the circles should be relative to each other. Using the edges of the existing shapes to describe the x-and-y positions of the new shapes was very accurate.
2. The speaker's statements were vague about scaling the distance between shapes and relative size of the shapes to each other. Despite the actual shapes being described accurately, final drawings still resulted in differences in shape positions. Some of the interpretations were more compact than the original, since the instructions didn't specify how dispersed each object was.
3. If we had to repeat the activity, we would make sure to be precise about how large each object is in proportion to the others. Since we all have line or grid paper, we could have used the number of lines to precisely measure the relative sizes of the shapes. Also being more specific about not just what direction the objects were spaced apart, but also how far in that direction would have been
